Introduction

- Ondansetron is a centrally acting 5-HT3 receptor antagonist.
  - Weak antagonism of 5-HT1A, 5-HT1B, and α, adrenergic receptors.
- When used for preventing emesis, ondansetron has a well-established safety profile.
- Most common adverse events include headache, malaise, constipation, diarrhea, and dizziness.1
- Large, pediatric symptomatic ingestions have not been well described.

Case Presentation

- A previously healthy 2-year-old female presented after suspected consumption of 58 (36 mg/kg) ondansetron 8 mg oral dissolving tablets (ODT) out a bottle of 60.
- Within one hour of ingestion, the child demonstrated difficulty ambulating, nystagmus, tremors, and sleepiness.
- The patient vomited and had worsening CNS depression, requiring intubation and mechanical ventilation.

Clinical Course

- Heart rate was 152 and blood pressure was 138/87 with lowest at 80/38.
- Exam significant for tremors, myoclonic jerks, dilated pupils.
- EKG showed sinus tachycardia with QTc of 507 ms.
- Electrolytes and hematocrit were within normal limits.
- Venous blood gas: pH 7.23, PCO2 56, PO2 44, HCO3 24
- Acetaminophen and salicylate were undetectable.
- Urine drug screen was negative for amphetamines, opiates, benzodiazepines, tetrahydrocannabinol, and cocaine.
- CT brain demonstrated no acute abnormalities.
- On the following day, the patient became more responsive.
  - Extubated and recovered without sequelae.
  - QTc prolongation resolved (442 ms).
- The patient was discharged home with aunt on day 3.

Case Discussion

- By history, this patient ingested the largest dose reported.
- First pass metabolism is reduced at higher dosages, thus bioavailability increases in overdose.1
- The mechanism of toxicity is uncertain but postulated:
  - To increase synaptic serotonin concentrations as a result of 5-HT3 receptor antagonism and decrease receptor selectivity.
  - To block α1 adrenergic receptors causing hypotension.
- Overdose experiences are limited with reports exhibiting similar symptoms to our case:
  - 12-month-old infant ingested 5.6-6.4 mg/kg with resultant respiratory failure and tonic-clonic seizure.2
  - 8-year-old boy with history of B-cell lymphoma ingested 1.25 mg/kg and developed hypotension requiring norepinephrine.3
- In the US, ondansetron ODT is typically dispensed in blister packs.
  - Because of hyperemesis gravidarum, the child’s mother obtained a bottle of 60 ondansetron ODT without blister packaging from a foreign pharmacy.
  - The ODT formulations have flavoring agents in the tablet making them palatable to children.
  - Zofran ODT – Strawberry flavor4
  - Lake Erie Medical Supply Generic ODT – Peppermint flavor4

Limitations

- Levels were unable to be obtained to confirm ondansetron exposure.
- Single case report cannot establish causality.

Conclusion

- Because of flavoring and rapid oral dissolution, ondansetron ODT can be attractive to children and result in severe consequences.
- Appropriate packaging such as blister packs may deter children from significant ingestion.
- In our patient, toxicity manifested as CNS depression requiring intubation, QTc prolongation, hypotension, and symptoms of serotonin excess.
